A comparison of sugar assimilation patterns has been made using 12 oral
bacterial isolates recovered from diseased and non-diseased patients.
Significant differences were demonstrated between isolates recovered from
diseased versus healthy sites. In addition, significant changes in colony
phenotype, growth frequency and morphological characteristics were found to
relate to predictive data generated from the same isolates. These
results suggest that clinical, pathogenic and colony phenotypic
characteristics may hold promise in predicting the behavior of oral
bacterial isolates in disease.
